Isomorphism on Hyp

October 26, 2014

Abstract

We show that isomorphism is not a complete Σ₁¹ equivalence relation even when restricted to the hyperarithmetic reals: If $E_1$ denotes the Σ₁¹ (even Δ₁¹) equivalence relation of [4] then for no Hyp function $f$ do we have $x E y$ iff $f(x)$ is isomorphic to $f(y)$ for all Hyp reals $x, y$. As a corollary to the proof we provide for each computable limit ordinal $\alpha$ a hyperarithmetic reduction of $\equiv_\alpha$ (elementary-equivalence for sentences of quantifier-rank less than $\alpha$) on arbitrary countable structures to isomorphism on countable structures of Scott rank at most $\alpha$.

In classical descriptive set theory, analytic equivalence relations (i.e., Σ₁¹ equivalence relations with parameters) are compared under the relation of Borel reducibility (see [3]). An important subclass of the Σ₁¹ equivalence relations is the class of isomorphism relations, i.e., the restrictions of the isomorphism relation on countable structures (viewed as an equivalence relation on reals coding such structures) to the models of a sentence of the infinitary logic $L_{\omega_1 \omega}$. Scott’s Theorem implies that the equivalence classes of any isomorphism relation are Borel, and therefore no isomorphism relation can be complete (under Borel reducibility) within the class of Σ₁¹ equivalence relations as a whole, as some of these have non-Borel equivalence classes.

The picture is different in the computable setting. It is shown in [1] that isomorphism on computable structures (viewed as an equivalence relation

∗The author wishes to thank the Austrian Science Fund (FWF) for its support through Project I 1238.
on natural numbers coding such structures), indeed on computable trees, is complete for $\Sigma^1_1$ equivalence relations under the natural analogue of Borel-reducibility for equivalence relations on numbers: $E$ is reducible to $F$ iff for some hyperarithmetic $f : \mathbb{N} \to \mathbb{N}$, $E(m, n)$ iff $F(f(m), f(n))$ for all $m, n$.

In [2] we surveyed the situation for classes of structures intermediate between the class of computable structures and the class of arbitrary countable structures. But one important case was not treated in that paper, the class of hyperarithmetic structures. The purpose of the present paper is to fill that gap.

By a $\Sigma^1_1$ equivalence relation we mean an equivalence relation on the reals which is $\Sigma^1_1$ definable without parameters (equivalently, with a hyperarithmetic real parameter). By a Hyp function from reals to reals we mean a function which is $\Delta^1_1$ (equivalently $\Sigma^1_1$) definable without parameters. (Hyp stands for Hyperarithmetic, which equals $\Delta^1_1$. ) A $\Sigma^1_1$ equivalence relation $F$ is complete on Hyp if for any $\Sigma^1_1$ equivalence relation $E$ there is a Hyp function $f$ such that for Hyp reals $x, y$: $xEy$ iff $f(x)Ff(y)$. In [2] the question of whether isomorphism is complete on Hyp was left open. The method of [1] showing that it is complete on the class of computable structures does not seem to work due to the absence of a Hyp enumeration of all Hyp reals, and the use of Scott’s Isomorphism Theorem to show that it is incomplete on the class of arbitrary countable structures does not work either, as if the countable structure $A$ has a Hyp code there need not be a Borel set $B$ with Hyp code which agrees on Hyp with the set of codes for structures isomorphic to $A$.

The solution comes from a deeper look at descriptive set theory and infinitary logic.

**Theorem 1** Isomorphism is not complete on Hyp: There is a $\Sigma^1_1$ (even $\Delta^1_1$) equivalence relation $E$ such that for no Hyp function $f$ do we have $xEy$ iff $f(x), f(y)$ code isomorphic structures (on $\omega$) for all Hyp reals $x, y$.

**The Relation $E_1$**

For $x : \omega \times \omega \to 2$ and $n \in \omega$ define $(x)_n : \omega \to 2$ by $(x)_n(i) = x(n, i)$. The equivalence relation $E_1$ is defined by:
$x \ E_1 y \iff (x)_n = (y)_n$ for large enough $n$.

$E_1$ is a Hyp equivalence relation. It was introduced in [4], where it was shown that there is no Borel reduction of $E_1$ to isomorphism on countable structures (or even to any orbit equivalence relation determined by a Borel action of a Polish group). First we show:

**Theorem 2** Suppose that $\alpha$ is a limit of admissible ordinals. Then $E_1$ is not Hyp-reducible to $\simeq$ (isomorphism) on $L_\alpha$: There is no total Hyp function $f$ such that for $x, y$ in $L_\alpha$, $x \ E_1 y \iff f(x), f(y)$ code isomorphic structures on $\omega$.

**Proof.** Suppose $f$ were a Hyp-reduction of $E_1$ to $\simeq$ on $L_\alpha$. For structures $A, B$ on $\omega$ define: $A \simeq_n B$ iff $A, B$ are isomorphic via an isomorphism which fixes $0, 1, \ldots, n - 1$.

Also write $x \ E_1^{n,k} y$ iff $(x)_i = (y)_i$ for $i \geq n$ and $(x)_i \upharpoonright k = (y)_i \upharpoonright k$ for $i < n$.

**Claim.** Suppose that $g : \omega \times \omega \to 2$ is Cohen-generic over $L_{\omega^1 k}$. Then for each $m, n$ there is a $k$ so that if $h : \omega \times \omega \to 2$ is Cohen-generic over $L_{\omega^1 k}$ and $g \ E_1^{n,k} h$ then $f(g) \simeq_m f(h)$.

**Proof.** For any $x : n \times \omega \to 2$ let $g^x$ be defined to agree with $g$ on $(\omega \setminus n) \times \omega$ and to agree with $x$ on $n \times \omega$. Also let $x_0 : n \times \omega \to 2$ take the constant value $0$. Note that $x = g \upharpoonright n \times \omega$ is Cohen-generic over $L_{\omega^1 k}[g \upharpoonright (\omega \setminus n) \times \omega]$ and let $k$ be large enough so that the condition $g \upharpoonright n \times \vec{k}$ on $x$ forces that the condition $g \upharpoonright n \times \vec{k}$ on $x$ forces that $f(g^x), f(g^{x_0})$ are Cohen-generic over $L_{\omega^1 k}$ and $g \ E_1^{n,k} h$ then $f(g), f(h)$ are both isomorphic to $f(g^{x_0})$ via an isomorphism sending $(0, 1, \ldots, m - 1)$ to $\vec{k}$ and therefore $f(g) \simeq_m f(h)$. □

(Claim)

Now inductively build sequences $((g^n, j_n) \mid n \in \omega)$ and $(\pi_n \mid 0 < n \in \omega)$ as follows (where the $g^n : \omega \times \omega \to 2$ are Cohen-generic over $L_{\omega^1 k}$, $0 < j_0 < j_1 < \cdots$ are natural numbers and $\pi_n$ is an isomorphism of $f(g^{n-1})$ onto $f(g^n)$). Fix an enumeration $(D_n \mid n \in \omega)$ in $L_\alpha$ of the dense sets for Cohen
forcing which are definable over $L_{\omega^1}$. Let $g^0 : \omega \times \omega \to 2$ be an arbitrary element of $L_\alpha$ which is Cohen-generic over $L_{\omega^1}$ and set $j_0 = 1$. Suppose that $g^n, j_n$ have been defined (also $\pi_n$ if $n > 0$). To obtain $g^{n+1}$ first apply the Claim to produce $k_n \geq j_n$ so that if $h$ is Cohen-generic over $L_{\omega^1}$ and $g^n \upharpoonright j_n \times k_n$ then $f(g^n) \approx_{j_n} f(h)$, where $l_n$ is greater than the images and pre-images of the numbers less than $n$ under the composition $\pi_n \circ \pi_{n-1} \circ \cdots \circ \pi_0$ (if $n = 0$ set $l_n = 0$). Then choose $j_{n+1}$ large enough so that some Cohen condition contained in $j_{n+1} \times j_{n+1}$, extending $g^n \upharpoonright j_n \times k_n$ and satisfied by $g^n$ belongs to the dense set $D_n$. Let $g^{n+1}$ be $g^n$ except at the pair $(j_{n+1}, j_{n+1})$ where its value is different from the value given by $g^n$. Finally, let $\pi_{n+1}$ be an isomorphism witnessing $f(g^n) \approx_{j_{n+1}} f(g^{n+1})$.

The resulting sequences have the following properties:

1. $f(g^n) \approx_{j_n} f(g^{n+1})$ where the $l_n$'s go to infinity. (thus the compositions $\pi_n \circ \pi_{n-1} \circ \cdots \circ \pi_0$ converge to a bijection).
2. The $j_n$'s and $k_n$'s increase to infinity (so the $g^n$'s converge).
3. $g^n, g^{n+1}$ agree on $j_{n+1} \times j_{n+1}$ but $(g^n)_{j_{n+1}}, (g^{n+1})_{j_{n+1}}$ differ somewhere.
4. $g$ is the limit of the $g^n$'s is Cohen-generic over $L_{\omega^1}$.

Then $g$ is not $E_1$-equivalent to $g^0$ by 3. Now recall our assumption that $\alpha$ is a limit of admissibles. This implies that wellfoundedness is absolute to $L_\alpha$ (i.e. any tree in $L_\alpha$ that is illfounded is also illfounded in $L_\alpha$) and from this it follows that any two structures which are countable in $L_\alpha$ and isomorphic are also isomorphic in $L_\alpha$ (build a tree of partial isomorphisms). It now follows that the sequence of $g^n$'s can be built in $L_\alpha$. Using 1 and 4, $f(g^0) \approx f(g)$. But this contradicts the assumption that $f$ is a reduction of $E_1$ to $\approx$ on $L_\alpha$.

Now to prove Theorem 1 we modify the above argument as follows. Suppose that $f$ were a Hyp reduction of $E_1$ to isomorphism on Hyp and choose a large enough computable ordinal $\alpha$ so that the code for $f$ belongs to $L_\alpha$. Fix a Hyp $g^0 : \omega \times \omega \to 2$ which is Cohen-generic over $L_\alpha$ and belongs to $L_\beta$ where $\beta$ is also computable. We would like to build sequences $((g^n, j^n) \mid n \in \omega)$ and $\pi_n \mid 0 < n < \omega)$ as above which are Hyp, as this will then yield the desired contradiction. This is possible provided there is a computable bound on the Scott ranks of all of the relevant structures $f(g^n)$, because if $\gamma$ is
a computable ordinal then the isomorphism relation on structures of Scott rank at most $\gamma$ is Hyp.

Note that if $g, h : \omega \times \omega \to 2$ and $gE_1h$ fails then $f(g), f(h)$ are non-isomorphic Hyp structures and therefore for some computable ordinal $\gamma$, $f(g) \not\equiv_\gamma f(h)$ (where $\equiv_\gamma$ is elementary equivalence for sentences of quantifier-rank less than $\gamma$). Now the set of pairs $(g, h)$ in $L_\beta$ such that $gE_1h$ fails is a Hyp set (i.e., it belongs to $L_{\omega_1^{ck}}$) and therefore there is some fixed computable ordinal $\gamma$ such that $f(g) \not\equiv_\gamma f(h)$ for all such pairs $(g, h)$.

Lemma 3 Suppose that $\alpha$ is a nonzero computable ordinal. Then there is a Hyp function $A \mapsto A^*$ from countable relational structures $A$ to countable structures $A^*$ such that:

(a) $A \cong B \implies A^* \cong B^*$.
(b) $A^* \equiv_\alpha B^* \implies A \equiv_\alpha B$.
(c) For each $A$, $A^*$ has Scott rank at most $\alpha$.

Proof. We define $A^*$ as follows:

a. An element of $A^*$ is an $\equiv_\alpha$ class $[a_1, \ldots, a_n]$ of a tuple $(a_1, \ldots, a_n)$ from $A$ (where two tuples are equivalent under $\equiv_\alpha$ iff they have the same length and satisfy the same formulas in $A$ of quantifier-rank less than $\alpha$).

b. $R^{A^*}([a_1, \ldots, a_n])$ iff $R^A(a_1, \ldots, a_n)$. (Thus the $n$-ary predicate $R^A$ becomes the unary predicate $R^{A^*}$). Note that $R^{A^*}$ is well-defined.

c. $[a_1, \ldots, a_n] * [b_1, \ldots, b_m] = [a_1, \ldots, a_n, b_1, \ldots, b_m]$ (i.e. we add a new binary concatenation function $*$).

d. $L_m([a_1, \ldots, a_n])$ iff $m = n$ (we add $\omega$-many new unary predicates $L_m$, $m \in \omega$).

Claim 1. If $A$ is isomorphic to $B$ then $A^*$ is isomorphic to $B^*$. (This is clear.)

Claim 2. If $A^* \equiv_\alpha B^*$ then $A \equiv_\alpha B$.

Proof. By induction on $\varphi = \varphi(x_1, \ldots, x_n)$ we show there is a formula $\varphi^* = \varphi^*(x^*)$ with the same quantifier-rank as $\varphi$ such that $A \vDash \varphi(a_1, \ldots, a_n)$ iff $A^* \vDash \varphi^*([a_1, \ldots, a_n])$. For atomic $\varphi = R(x_1, \ldots, x_n)$ we may take $\varphi^*$ to be $R(x^*)$. And $(\sim \varphi)^* = \sim \varphi^*$, $(\varphi \land \psi)^* = \varphi^* \land \psi^*$.
If \( \varphi \) is \( \exists y \psi(x_1, \ldots, x_n, y) \) then take \( \varphi^* \) to be \( \exists y^* (\psi^* (x^* * y^*)) \) and \( L_1(y^*) \).

We have:

\[ A \models \exists y \psi(a_1, \ldots, a_n, y) \text{ iff } A \models \psi(a_1, \ldots, a_n, a_{n+1}) \text{ for some } a_{n+1} \text{ iff } A^* \models \psi^* ([a_1, \ldots, a_n] * a_{n+1}) \text{ iff } L_1([a_{n+1}]) \text{ for some } a_{n+1} \text{ iff } A^* \models \exists y^* (\psi^* ([a_1, \ldots, a_n] * y^*)) \text{ and } L_1(y^*). \]

\[ \square \text{ (Claim 2.)} \]

**Claim 3.** Suppose that \( (A^*, [\vec{a}_1], \ldots, [\vec{a}_n]) \equiv_\alpha (A^*, [\vec{b}_1], \ldots, [\vec{b}_n]) \). Then \( [\vec{a}_i] = [\vec{b}_i] \) for each \( i \) (and therefore \( A^* \) has Scott rank at most \( \alpha \)).

**Proof.** The hypothesis implies that \( (A^*, [\vec{a}_i]) \equiv_\alpha (A^*, [\vec{b}_i]) \) for each \( i \). And it is enough to show that \( \vec{a}_i \equiv_\alpha \vec{b}_i \) for each \( i \). If \( \varphi \) has quantifier-rank less than \( \alpha \) then \( A \models \varphi(\vec{a}_i) \text{ iff } A^* \models \varphi^*([\vec{a}_i]) \text{ iff } A^* \models \varphi^*([\vec{b}_i]) \text{ iff } A \models \varphi(\vec{b}_i) \). So as \( \varphi^* \) also has rank less than \( \alpha \) we are done. \( \square \) (Lemma 3)

Now recall that we have computable ordinals \( \beta < \gamma \) such that for \( g, h \) in \( L_\beta \), \( gE_1 h \text{ iff } f(g) \equiv_\gamma f(h) \). Applying the Lemma when \( \alpha \) is equal to \( \gamma \) we obtain for \( g, h \) in \( L_\beta \):

\[ gE_1 h \rightarrow f(g) \simeq f(h) \rightarrow f(g)^* \simeq f(h)^* \]

and

\[ f(g)^* \simeq f(h)^* \rightarrow f(g)^* \equiv_\gamma f(h)^* \rightarrow f(g) \equiv_\gamma f(h) \rightarrow gE_1 h \]

and therefore have a Hyp reduction of \( E_1 \) on \( L_\beta \) to isomorphism on Hyp whose range consists of structures of Scott rank bounded by a fixed computable ordinal. As explained above, this allows us to repeat the proof of Theorem 2 to reach a contradiction from the assumption of a Hyp reduction \( E_1 \) to isomorphism on Hyp. This completes the proof of Theorem 1.

As a corollary to the proof of Lemma 3 we also obtain the following, which may be of independent interest.
**Theorem 4** For each computable limit ordinal \( \alpha \) there is a Hyp reduction of the equivalence relation \( \equiv_\alpha \) on countable structures to isomorphism on countable structures of Scott rank at most \( \alpha \).

**Proof.** For each countable structure \( A \) and \( \beta < \alpha \) let \( A'_\beta \) be the structure of Scott rank at most \( \beta \) defined in the proof of Lemma 3. Now form \( A^* \) by taking the union of disjoint copies of the structures \( A'_\beta \), \( \beta < \alpha \), expanded with the quasiorder \( x_\beta_0 \leq x_\beta_1 \) iff \( \beta_0 \leq \beta_1 \) when \( x_\beta_i \) belongs to the copy of \( A'_\beta \). Thus \( A^* \) consists of the structures \( A'_\beta \), \( \beta < \alpha \), ordered in ordertype \( \alpha \).

If \( A \equiv_\alpha B \), then for each \( \beta < \alpha \), \( A'_\beta \) is isomorphic to \( B'_\beta \) via the isomorphism which sends \( [a_1, \ldots, a_n] \) to \( [b_1, \ldots, b_n] \), where \( [b_1, \ldots, b_n] \) satisfies the same formulas of quantifier rank at most \( \beta \) as \( [a_1, \ldots, a_n] \) (the fact that \( A \equiv_\alpha B \) implies that there is such a unique \( [b_1, \ldots, b_n] \)). It follows that \( A^* \) is isomorphic to \( B^* \). Conversely, if \( A^* \) is isomorphic to \( B^* \) then Claim 2 of the proof of Lemma 3 implies that \( A \) and \( B \) satisfy the same sentences of quantifier rank less than \( \alpha \) and therefore \( A \equiv_\alpha B \).

Finally, note that Claim 3 of the proof of Lemma 3 implies that \( A^* \) has Scott rank at most \( \alpha \). \( \square \)

**Remarks.** The results of this paper relativise in the natural way: For any real parameter \( x \), no reduction to isomorphism of \( E_1 \) restricted to the reals Hyp in \( x \) is Hyp in \( x \). From this one can infer the Kechris-Louveau result that there is no Borel reduction of the entire \( E_1 \) to isomorphism on countable structures.

**Question.** Suppose that \( E \) is a \( \Sigma^1_1 \) equivalence relation and \( E_1 \) is not Hyp-reducible to \( E \) on Hyp. Then is \( E \) Hyp-reducible to isomorphism on Hyp?
