THE CONSISTENCY OF $b = \kappa$ AND $s = \kappa^+$

VERA FISCHER AND JURIS STEPRANS

Abstract. Using finite support iteration of c.c.c. partial orders we provide a model of $b = \kappa < s = \kappa^+$ for $\kappa$ an arbitrary regular, uncountable cardinal.

1. Introduction

S. Shelah obtains the consistency of $b = \omega_1 < s = \omega_2$ using countable support iteration of a proper forcing notion which adds a real not split by the ground model reals and which satisfies the almost $\omega$-bounding property (see [10]). This paper will show that it is possible to find ccc suborders of Shelah's original order which behave very similarly to the larger order. Being ccc, it is possible to iterate them with finite support. Assuming that the covering number of the meager ideal is $\kappa$ it will be shown that for any unbounded family $\mathcal{H} \subseteq {}^\omega \omega$ of size $\kappa$, such that every subfamily of size smaller than $\kappa$ is dominated by an element of $\mathcal{H}$, there is a ccc forcing notion which preserves $\mathcal{H}$ unbounded and adds a real not split by the ground model reals. Thus under a suitable finite support iteration of length $\kappa^+$ of ccc forcing notions, the consistency of $b = \kappa < s = \kappa^+$ for arbitrary regular $\kappa$ will be established (section 6). Using a different model Joerg Brendle obtains the consistency of $b = \omega_1 < s = \kappa$ for arbitrary regular $\kappa$ (see [5] Theorem 12.16 and [4]).

2. Preliminaries

Let $f$ and $g$ be functions in $\omega^n$. The function $f$ is dominated by the function $g$ if and only if there is $n \in \omega$ such that $f \leq_n g$, i.e. $(\forall i \geq n)(f(i) \leq g(i))$. Then $\prec^* = \bigcup_{n \in \omega} \leq_n$ is called the bounding relation on $\omega^n$. A family of functions $\mathcal{F}$ in $\omega^n$ is dominated by the function $g$, denoted $\mathcal{F} \prec^* g$ if and only if for every $f \in \mathcal{F}$, $f <^* g$. Also $\mathcal{F}$ is unbounded (equiv. not dominated) if and only if there is no function $g$ which dominates it. Then the bounding number is defined as the minimal size of an unbounded family. That is $b = \min\{|B| : B \subseteq {}^\omega \omega$ and $B$ is unbounded}. A family $S$ of infinite subsets of $\omega$ is

\footnotesize{\begin{quote}
\text{2000 Mathematics Subject Classification: 03E17, 03E35, 03E50}
\end{quote}}
splitting if and only if for every \( A \in [\omega]^\omega \) there is \( B \in S \) such that \( A \cap B \) and \( A \cap B^c \) are infinite. Then the splitting number is defined as the minimal size of a splitting family. That is \( s = \min \{|S| : S \subseteq [\omega]^\omega \text{ and } S \text{ is splitting}\} \). A family \( \mathcal{H} \subseteq [\omega]^\omega \) is splitting \( [<\omega,\text{ directed if every subfamily of size less than } |\mathcal{H}| \text{ is dominated by an element of } \mathcal{H} \).

3. CENTRED FAMILIES OF PURE CONDITIONS

The notion of logarithmic measure is due to S. Shelah. In the presentation of logarithmic measures and their basic properties (Definitions 3.1, 3.4, 3.8, Lemmas 3.3, 3.5, 3.7) we follow [1].

**Definition 3.1.** Let \( s \subseteq \omega \) and let \( h : [s]^{<\omega} \to \omega \), where \([s]^{<\omega} \) is the family of finite subsets of \( s \). Then \( h \) is a logarithmic measure if \( \forall A \in [s]^{<\omega}, \forall A_0, A_1 \text{ such that } A = A_0 \cup A_1, h(A_i) \geq h(A) - 1 \text{ for } i = 0 \text{ or } i = 1 \) unless \( h(A) = 0 \). Whenever \( s \) is a finite set and \( h \) a logarithmic measure on \( s \), the pair \( (s, h) \) is called a finite logarithmic measure. The value \( h(s) = \|x\| \) is called the level of \( x \), the underlying set of integers \( s \) is denoted \( \text{int}(x) \).

**Definition 3.2.** Whenever \( h \) is a finite logarithmic measure on \( x \) and \( e \subseteq x \) is such that \( h(e) > 0 \), we will say that \( e \) is \( h \)-positive.

**Lemma 3.3.** If \( h \) is a logarithmic measure and \( h(A_0 \cup \cdots \cup A_{n-1}) \geq \ell + 1 \) then \( h(A_j) \geq \ell - j \) for some \( j, 0 \leq j \leq n - 1 \).

**Definition 3.4.** Let \( P \subseteq [\omega]^{<\omega} \) be an upwards closed family. Then \( P \) induces a logarithmic measure \( h \) on \([\omega]^{<\omega} \) defined inductively on \(|s|\) for \( s \in [\omega]^{<\omega} \) as follows:

1. \( h(e) \geq 0 \) for every \( e \in [\omega]^{<\omega} \)
2. \( h(e) > 0 \) iff \( e \in P \)
3. for \( \ell \geq 1 \), \( h(e) \geq \ell + 1 \) iff \( |e| > 1 \) and whenever \( e_0, e_1 \subseteq e \) are such that \( e = e_0 \cup e_1 \), then \( h(e_0) \geq \ell \) or \( h(e_1) \geq \ell \).

Then \( h(e) = \ell \) if \( \ell \) is maximal for which \( h(e) \geq \ell \). The elements of \( P \) are called positive sets and \( h \) is said to be induced by \( P \).

**Corollary 3.5.** If \( h \) is a logarithmic measure induced by positive sets and \( h(e) \geq \ell \), then for every \( a \) such that \( e \subseteq a \), \( h(a) \geq \ell \).

**Example 1** (Shelah, [11]). Let \( P \subseteq [\omega]^{<\omega} \) be the family of sets containing at least two points and \( h \) the logarithmic measure induced by \( P \). Then \( \forall x \in P, h(x) = \min \{i : |x| \leq 2^i\} \). This measure is called standard logarithmic measure.

**Remark 3.6.** From now on we assume that all logarithmic measures have the additional property that singletons are not positive sets.
Lemma 3.7. Let $P \subseteq [\omega]^<\omega$ be an upwards closed family and let $h$ be the logarithmic measure induced by $P$. Then if for every $n \in \omega$ and every partition of $\omega$ into $n$ sets $\omega = A_0 \cup \cdots \cup A_{n-1}$ there is $j \in n$ such that $A_j$ contains a positive set, then for every $k \in \omega$, for every $n \in \omega$ and partition of $\omega$ into $n$ sets $\omega = A_0 \cup \cdots \cup A_{n-1}$ there is $j \in n$ such that $A_j$ contains a set of $h$ measure greater or equal $k$.

Definition 3.8. Let $Q$ be the set of all pairs $(u, T)$ where $u \in [\omega]^<\omega$ and $T = \langle (s_i, h_i) : i \in \omega \rangle$ is a sequence of finite logarithmic measures such that $\max u < \min s_0$, $\max s_i < \min s_{i+1}$ for all $i \in \omega$ and $(h_i(s_i) : i \in \omega)$ is unbounded. If $u = \emptyset$ we say that $(\emptyset, T)$ is a pure condition and denote it by $T$. The underlying set of integers $\bigcup \{s_i : s \in \omega \}$ is denoted $\operatorname{int}(T)$. We say that $(u_1, T_1)$ is extended by $(u_2, T_2)$, where $T_\ell = \langle (s_i^\ell, h_i^\ell) : i \in \omega \rangle$ for $\ell = 1, 2$, and denote it by $(u_2, T_2) \leq (u_1, T_1)$ if the following conditions hold:

1. $u_2$ is an end-extension of $u_1$ and $u_2 \backslash u_1 \subseteq \operatorname{int}(T_1)$
2. $\operatorname{int}(T_2) \subseteq \operatorname{int}(T_1)$ and furthermore there is an infinite sequence $\langle B_i : i \in \omega \rangle$ of finite subsets of $\omega$ such that $\max u_2 < \min s_j^1$ for $j = \min B_0$, $\max(B_i) < \min(B_{i+1})$ and $s_j^2 \subseteq \bigcup \{s_j^1 : j \in B_i \}$.
3. For every subset $e$ of $s_j^2$ such that $h_j^2(e) > 0$ there is $j \in B_i$ such that $h_j^2(e \cap s_j^1) > 0$.

In case that $u_1 = u_2$, $(u_2, T_2)$ is called a pure extension of $(u_1, T_1)$.

Whenever $T = \langle t_i : i \in \omega \rangle$ is a pure condition and $k \in \omega$, let $i_T(k) = \min \{i : k < \min \operatorname{int}(t_i) \}$ and let $T \backslash k = T_{i_T(k)} = \langle t_i : i \geq i_T(k) \rangle$. For $u \in [\omega]^<\omega$ let $(u, T) = (u, T \backslash u) = (u, T_{i_T(\max u)})$. Note that if $R \subseteq T$ and $k \in \operatorname{int}(R)$, then $R \backslash k \leq T \backslash k$.

Definition 3.9. If $\mathcal{F}$ is a family of pure conditions, then $Q(\mathcal{F})$ is the suborder of $Q$ consisting of all $(u, T) \in Q$ such that $\exists R \in \mathcal{F}(R \subseteq T)$.

Observe that if $C$ is a centred family of pure conditions, then any two conditions in $Q(C)$ with equal stems have a common extension in $Q(C)$ and so $Q(C)$ is $\sigma$-centred. From now on by centred family we mean a centred family of pure conditions. We assume also that all centred families are closed with respect to final segments, that is if $C$ is a centred family and $T \in C$ then $T \backslash v \in C$ for every $v \in [\omega]^<\omega$.

Lemma 3.10. Any two conditions of $Q(C)$ are compatible as conditions in $Q(C)$ if and only if they are compatible in $Q$.

Lemma 3.11. Let $T = \langle t_i : i \in \omega \rangle$, where $t_i = (s_i, h_i)$, be a pure condition and $\omega = A_0 \cup \cdots \cup A_{n-1}$ a finite partition. Then there is $j \in n$ such that $\langle h_i(s_i \cap A_j) : i \in \omega \rangle$ is unbounded.
Definition 3.12. Whenever \( T = \langle (s_i, h_i) : i \in \omega \rangle \) is a pure condition and \( A \subseteq \omega \), let \( T \upharpoonright A = \langle (s_i \cap A, h_i \upharpoonright \mathcal{P}(s_i \cap A)) : i \in \omega \rangle \).

If \( T = \langle (s_i, h_i) : i \in \omega \rangle \) is a pure condition, \( A \subseteq \omega \) and \( \langle h_i(s_i \cap A) : i \in \omega \rangle \) is bounded, then \( T \) has no pure extension \( R \) with \( \text{int}(R) \subseteq A \).

A pure condition \( T \), compatible with every element of a family of pure conditions \( \mathcal{F} \), is said to be compatible with \( \mathcal{F} \), denoted \( T \not\perp \mathcal{F} \). If \( C' \) is a centered family such that \( C \subseteq Q(C') \) then \( C' \) is said to extend \( C \).

Lemma 3.13. Let \( C \) be a centered family, \( T \) a pure condition compatible with \( C \) and \( \omega = A_0 \cup \cdots \cup A_{n-1} \) a finite partition. Then there is \( j \in n \) such that \( T \upharpoonright A_j \) is a pure condition compatible with \( C \).

Proof. By Lemma 3.11 \( I = \{ j \in n : T \upharpoonright A_j \) is a pure condition\} \( \neq \emptyset \).

Suppose for every \( j \in I \) there is \( T_j \in C_j \) such that \( T \upharpoonright A_j \) and \( T_j \) are incompatible. However \( I \) is finite, \( C \) is centered and so \( \exists X \in C \) such that \( \forall j \in I(X \leq T_j) \). By hypothesis \( X \) and \( T \) have a common extension \( R \in Q \). By Lemma 3.11 \( \exists n \) such that \( R \upharpoonright A_i \) is a pure condition. However \( R \upharpoonright A_i \leq T \upharpoonright A_i \) and so \( i \in I \). Also \( R \upharpoonright A_i \leq R \leq X \leq T_i \) and so \( T_i \) and \( T \upharpoonright A_i \) are compatible which is a contradiction. \( \square \)

Definition 3.14. Let \( Q_{\text{fin}} \) be the partial order of all sequences \( \bar{r} = \langle r_0, \ldots, r_n \rangle, n \in \omega \) of finite logarithmic measures \( r_i = (s_i, h_i) \) such that for all \( i \in n \), \( \max(s_i) < \min(s_{i+1}) \) and \( h_i(s_i) < h_{i+1}(s_{i+1}) \) with extension relation end-extension. The level of the sequence \( \bar{r} = \langle r_0, \ldots, r_n \rangle \) is the level of \( r_n \), denoted \( \| \bar{r} \| \).

Definition 3.15. The sequence \( \bar{r} \in Q_{\text{fin}} \) extends the pure condition \( T \), if there is \( R \leq T \) such that \( \bar{r} \subseteq R \). The finite logarithmic measure \( r \) extends \( T \), if \( \bar{r} = \langle r \rangle \) extends \( T \).

Definition 3.16. Let \( \tau = \langle T_n : n \in \omega \rangle \) be a sequence of pure conditions such that \( \forall n(T_{n+1} \leq T_n) \). Then \( \mathbb{P}_\tau \) is the suborder of \( Q_{\text{fin}} \) of all \( \bar{r} \) such that \( \forall i \in \| \bar{r} \|(r_i \leq T_i) \) where \( j_0 = 0 \) and for \( i \geq 1, j_i = \max(\text{int}(r_{i-1})) \).

Lemma 3.17. Let \( X \) be a pure condition compatible with \( \tau, n \in \omega \). Then \( D_\tau(X, n) = \{ \bar{r} \in \mathbb{P}_\tau : \exists r_j \in \bar{r}(r_j \leq X \text{ and } \| r_j \| \geq n) \} \) is dense.

Proof. Let \( \bar{r} \in \mathbb{P}_\tau \) and let \( j = \max(\text{int}(\bar{r})) \). Since \( T_0 \setminus \text{int}(\bar{r}) \) and \( X \) are compatible, there is a finite logarithmic measure \( r \), such that \( \| r \| > \max\{\| \bar{r} \|, n\} \), which is their common extension. Then \( \bar{r} \cap (r) \) is an extension of \( \bar{r} \) which belongs to \( D_\tau(X, n) \). \( \square \)

Corollary 3.18. Let \( C \) be a centered family, such that \( \forall X \in C(X \not\perp \tau) \) and let \( G \) be a \( \mathbb{P}_\tau \)-generic filter. Then \( R = \cup R = \langle r_i : i \in \omega \rangle \) is a pure condition of finite logarithmic measures of strictly increasing levels. In \( V[G] \) there is a centered family \( C' \) such that \( |C'| = |C| \) and \( C \cup \tau \subseteq C' \).
Proof. For every $X \in C$, $n \in \omega$ the set $D_r(X, n)$ is dense in $\mathbb{P}_r$ and so $G \cap D_r(X, n) \neq \emptyset$. Then $I_X = \{i : r_i \leq X\}$ is infinite and so $R \cap X := \langle r_i : i \in I_X \rangle$ is pure condition which is a common extension of $R$ and $X$. Furthermore if $X \leq Y$ then $I_X \subseteq I_Y$ which implies $R \cap X \leq R \cap Y$ and so the family $\{R \cap X\}_{X \in C}$ is centred. \hfill $\square$

4. PREPROCESSED CONDITIONS

We use the fact that all reals have simple names of the form $\dot{f} = \bigcup\{\langle i, j_p^i, p \rangle : p \in A_i, i \in \omega, j_p^i \in \omega\}$ where for every $i \in \omega$, $A_i = A_i(\dot{f})$ is a maximal antichain of conditions deciding $\dot{f}(i)$.

**Definition 4.1.** Let $C$ be a centred family and let $\dot{f}$ be a $Q(C)$-name for a real. Then $\dot{f}$ is a good name if for every centred family $C'$ extending $C$, $\dot{f}$ is a $Q(C')$-name for a real.

**Remark 4.2.** If $\dot{f}$ is a $Q(C)$-name for a real and there is a centred family $C'$ extending $C$ such that $\dot{f}$ is not a $Q(C')$-name for a real, then there is a centred family $C''$ extending $C$, which has the same cardinality as $C$ such that $\dot{f}$ is not a $Q(C'')$-name for a real.

**Definition 4.3.** Let $C$ be a centred family, $\dot{f}$ a good $Q(C)$-name for a real, $i, k \in \omega$. A pure condition $T \in Q(C)$ such that $k < \min \text{int}(T)$ is preprocessed for $\dot{f}(i)$, $k$, $C$ (note that Abraham [1] uses the same terminology) if for every $v \subseteq k$ the following holds. If there is a centred family $C'$ extending $C$ such that $\|C'\| = \|C\|$, a pure condition $R \in Q(C')$ extending $T$ and a condition $q \in A_i(\dot{f})$ such that $(v, R) \leq q$, then there is $p \in A_i(\dot{f})$ such that $(v, T) \leq p$.

**Remark 4.4.** Let $C$ be a centred family, $\dot{f}$ a good $Q(C)$-name for a real, $i, k \in \omega$, $T \in Q(C)$ a pure condition preprocessed for $\dot{f}(i)$, $k$, $C$. Let $C'$ be a centred family extending $C$, $\|C'\| = \|C\|$ and $T' \in Q(C')$ a pure extension of $T$. Then $T'$ is preprocessed for $\dot{f}(i)$, $k$, $C'$.

**Corollary 4.5.** Let $C$ be a centered family, $\dot{f}$ a good $Q(C)$-name for a real, $\tau = \langle T_n : n \in \omega \rangle \subseteq Q(C)$ a sequence of pure conditions such that $\forall n \forall i \leq n T_n$ is preprocessed for $\dot{f}(i)$, $n$, $C$ and let $G$ be a $\mathbb{P}_{r^-}$ generic filter, $R = \bigcup G = \langle r_i : i \in \omega \rangle$. Then in $V[G]$ there is a centred family $C'$, $C \cup \{R\} \subseteq Q(C')$, $\|C'\| = \|C\|$ such that for all $n \in \omega$, $k \in \text{int}(R_n)$, $R_n\backslash k$ is preprocessed for $\dot{f}(n)$, $k$, $C'$ where $R_n = R \backslash \text{int}(r_{n-1})$.

**Proof.** Repeat the proof of Corollary 3.18 to obtain the family $C'$. Let $n \in \omega$, $k \in \text{int}(R_n)$ and $i_{R_n}(k) = m$. Then $k \leq j_m = \max \text{int}(r_{m-1})$. By definition $T_{j_m}$ is preprocessed for $\dot{f}(n)$, $j_m$, $C$ (note $n \leq m \leq j_m$). Since $R_n\backslash k = R_m \leq T_{j_m}$, $R_n\backslash k$ is preprocessed for $\dot{f}(n)$, $k$, $C'$. \hfill $\square$
5. Induced Logarithmic Measures

For completeness we state $MA_{\text{countable}}(\kappa)$ (see [8]).

**Definition 5.1.** $MA_{\text{countable}}(\kappa)$ is the statement: for every countable partial order $\mathbb{P}$ and every family $D$, $|D| < \kappa$ of dense subsets of $\mathbb{P}$ there is a filter $G \subseteq \mathbb{P}$ such that $\forall D \in D(G \cap D \neq \emptyset)$.

Let $\mathcal{M}$ be the ideal of meager subsets of the real line. Recall that the covering number of $\mathcal{M}$, $\text{cov}(\mathcal{M})$ is the minimal size of a family of meager sets which covers the real line. For every regular uncountable cardinal $\kappa$, $\text{cov}(\mathcal{M}) \geq \kappa$ if and only if $MA_{\text{countable}}(\kappa)$ (see [3]).

**Lemma 5.2.** Let $C$ be a centred family, $|C| < \text{cov}(\mathcal{M})$, $\dot{f}$ a good $Q(C)$-name for a real, $n \in \omega$, $T = ((s_i, h_i) : i \in \omega) \in Q(C)$ such that $\forall k \in \text{int}(T)$, $T \setminus k$ is preprocessed for $\dot{f}(n)$, $k$, $C$. Let $v \in [\omega]^{<\omega}$. Then the logarithmic measure induced by the family $\mathcal{P}_v(T, \dot{f}(n))$ consisting of all $x \in [\text{int}(T)]^{<\omega}$ such that $\exists i \in \omega(h_i(x \cap s_i) > 0)$ and $\exists w \subseteq x \exists p \in A_n(\dot{f})(v \cup w, T \setminus x \leq p)$ takes arbitrarily high values.

**Proof.** To see that the induced measures takes arbitrarily high values consider an arbitrary finite partition $\omega = A_0 \cup \cdots \cup A_{M-1}$. By Lemma 3.13 there is $j \in M$ such that $T \upharpoonright A_j$ is a pure condition compatible with $C$. By $|C| < \text{cov}(\mathcal{M})$ and Corollary 3.18 there is a centred family $C'$ extending $C$, $|C'| = |C|$ and a pure extension $R \in Q(C')$ of $T \upharpoonright A_j$. Then $\dot{f}$ is a $Q(C')$-name for a real and so $A_n(\dot{f})$ is a maximal antichain in $Q(C')$. Therefore there is a common extension $(v \cup w, R') \in Q(C')$ of $(v, R)$ and some $q \in A_n(\dot{f})$. Let $\bar{r}$ be a finite subsequence of $R$ such that $w \subseteq x = \text{int}(\bar{r})$. We can assume that $|\bar{r}| > 0$. However $R \leq T$ and so there is $i \in \omega$ such that $h_i(x \cap s_i) > 0$. Since $R' \leq T$ and $T \setminus x$ is preprocessed for $\dot{f}(n)$, max $x$, $C$, there is $p \in A_n(\dot{f})$ such that $(v \cup w, T \setminus x \leq p)$.

**Corollary 5.3.** Let $C$ be a centred family, $|C| < \text{cov}(\mathcal{M})$, $\dot{f}$ a good $Q(C)$-name for a real, $m, n \in \omega$, $T = ((s_i, h_i) : i \in \omega) \in Q(C)$ such that $\forall k \in \text{int}(T)$, $T \setminus k$ is preprocessed for $\dot{f}(n)$, $k$, $C$. Then the logarithmic measure induced by the family $\mathcal{P}_m(T, \dot{f}(n))$ of all $x \in [\text{int}(T)]^{<\omega}$ such that $\exists i \in \omega(h_i(x \cap s_i) > 0)$ and $\forall v \subseteq m \exists w \subseteq x \exists p \in A_n(\dot{f})(v \cup w, T \setminus x \leq p)$ takes arbitrarily high values.

**Proof.** Let $v_0, \ldots, v_{L-1}$ enumerate the subsets of $m$ and let $\omega = A_0 \cup \cdots \cup A_{M-1}$ be a finite partition. By Lemma 3.13 there is $j \in M$ such that $T \upharpoonright A_j$ is a pure condition compatible with $C$. By $|C| < \text{cov}(\mathcal{M})$ and Corollary 3.18 there is a centred family $C'$ extending $C$, $|C'| = |C|$ and a pure extension $R \in Q(C')$ of $T \upharpoonright A_j$. For every $k \in \text{int}(R)$,
R\k is preprocessed for \hat{f}(n), k, C'. Therefore by Lemma 5.2 for every i \in L there is \( x_i \in P_n(R, \hat{f}(n)) \). It will be shown that \( x = \bigcup_{i \in L} x_i \in P_m(T, \hat{f}(n)) \). Let \( v \subseteq m \). Then \( v = v_i \) for some \( i \in L \). Since \( x_i \in P_{v_i}(R, \hat{f}(n)) \) there is \( w_i \subseteq x_i \) and \( q_i \in A_n(\hat{f}) \) such that \( (v_i \cup w_i, R\setminus x_i) \leq q_i \), and so \( (v_i \cup w_i, R\setminus x) \leq q_i \). However \( R \leq T \), \( C' \) extends \( C \), \( |C'| = |C| \) and \( T\setminus x \) is preprocessed for \( \hat{f}(n) \), max \( x \), \( C \). Then \( \forall i \in L \) there is \( p_i \in A_n(\hat{f}) \) such that \( (v_i \cup w_i, T\setminus x) \leq p_i \). □

Until the end of the section let \( C \) be a centred family, \(|C| < \text{cov}(\mathcal{M})\), \( \hat{f} \) a good \( Q(C) \)-name for a real, \( T = \langle t_i : i \in \omega \rangle \in Q(C) \) a pure condition such that for all \( n \in \omega \), \( k \in \text{int}(T_n) \), \( T\setminus k \) is preprocessed for \( \hat{f}(n), k, C \), where \( T_n = T\setminus \text{int}(t_{n-1}) \).

**Definition 5.4.** Let \( \mathbb{P}(C, T, \hat{f}) \) be the suborder of \( Q_{fin} \) of all sequences \( \bar{r} = \langle (x_i, g_i) : i \in \bar{l} \rangle \) extending \( T \), such that \( \forall i \in \bar{l} \forall v \subseteq \max x_{i-1} \forall s \subseteq x_i \) such that \( g_i(s) > 0 \), \( \exists w \subseteq s \exists p \in A_i(\hat{f})((v \cup w, T\setminus s) \leq p) \).

**Lemma 5.5.** Let \( X \in Q(C) \), \( n \in \omega \). Then \( D_{X,n}(C, T, \hat{f}) = \{ \bar{r} \in \mathbb{P}(C, T, \hat{f}) : \exists r_j \in \bar{r} (r_j \leq X \text{ and } \|r_j\| \geq n) \} \) is dense.

**Proof.** Let \( \bar{r} \in \mathbb{P}(C, T, \hat{f}) \), \( j = |\bar{r}| \), \( m = \text{max int}(\bar{r}) \). Let \( Y \in C \) be a common extension of \( X \) and \( T \setminus \text{int}(\bar{r}) \). For every \( k \in \text{int}(Y) \), \( Y\setminus k \leq T_j\setminus k \) and so \( Y\setminus k \) is preprocessed for \( \hat{f}(j), k, C \). By Corollary 5.3 the logarithmic measure \( h \) induced by \( \mathcal{P}_m(Y, \hat{f}(j)) \) takes arbitrarily high values and so \( \exists x (h(x) > \max \{\|\bar{r}\|, n\}) \). Let \( r = (x, h \upharpoonright \mathcal{P}(x)), v \subseteq m, s \subseteq x \) such that \( h(s) > 0 \). By definition of \( h \) there are \( w \subseteq s \) and \( q \in A_j(\hat{f}) \) such that \( (v \cup w, Y\setminus s) \leq q \). But \( T_j\setminus s \) is preprocessed for \( \hat{f}(j) \), max \( s, C \) and so there is \( p \in A_j(\hat{f}) \) such that \( (v \cup w, T\setminus s) \leq p \). □

**Corollary 5.6.** Let \( G \) be a filter in \( \mathbb{P}(C, T, \hat{f}) \) meeting \( D_{X,n}(C, T, \hat{f}) \) for all \( X \in C \), \( n \in \omega \), \( R = \bigcup G = \langle r_i : i \in \omega \rangle \). Then \( \forall \forall v \subseteq i \forall s \subseteq \text{int}(r_i) \) which is \( r_i \)-positive \( \exists w \subseteq s \exists p \in A_i(\hat{f})((v \cup w, R) \leq p) \). In \( V[G] \) there is a centred family \( C' \) such that \( C \cup \{R\} \subseteq Q(C') \) and \(|C'| = |C|\).

**Proof.** Let \( i \in \omega, v \subseteq i \) and \( s \subseteq \text{int}(r_i) \) which is \( r_i \)-positive. Then by definition there are \( w \subseteq s \) and \( p \in A_i(\hat{f}) \) such that \( (v \cup w, T\setminus s) \leq p \). However \( R \leq T \) and so \( (v \cup w, R) = (v \cup w, R\setminus s) \leq p \). □

**Remark 5.7.** If \( X \notin Q(C) \), then the analogous \( D_{X,n}(C, T, \hat{f}) \) is not necessarily dense. In fact the notion of a preprocessed condition is not defined for \( X \). Thus \( \mathbb{P}(C, T, \hat{f}) \) and \( \mathbb{P}_\tau \) are distinct forcing notions.
6. Mimicking the Almost Bounding Property

**Theorem 6.1.** Let $\kappa$ be a regular uncountable cardinal, $\text{cov}(\mathcal{M}) = \kappa$, $\mathcal{H} \subseteq {}^\omega \omega$, $|\mathcal{H}| = \kappa$ an unbounded, $<^*\text{-directed family}, C$ a centred family, $|C| < \kappa$ and let $\dot{f}$ be a good $Q(C)$-name for a real. Then there are a centred family $C'$ extending $C$, $|C'| = |C|$ and $h \in \mathcal{H}$ such that for every centred family $C''$ extending $C'$, $\Vdash_{Q(C'')}{\check{h} <^* \dot{f}}$.

**Proof.** Let $T \in Q(C)$. There is a centered family $C_0$ extending $C$, $|C_0| = |C|$ and a sequence $\tau = \langle T_n : n \in \omega \rangle \subseteq Q(C)$ such that for all $n$, $T_n \leq T_{n-1}$ where $T_{-1} = T$ and $\forall n \forall i \leq n, T_n$ is preprocessed for $\dot{f}(i), n, C_0$. By Corollary 4.5 and $|C| < \text{cov}(\mathcal{M})$, there is a centred family $C_1$ extending $C$, $|C_1| = |C|$ and a pure condition $T_1 \in Q(C_1)$ such that if $T_1 = \langle t_i^i : i \in \omega \rangle$ then $\forall n \in \omega \forall k \in \text{int}(T_1 \setminus \{t_{n-1}^i\}), T_1 \setminus k$ is preprocessed for $\dot{f}(n), k, C_1$. By $|C_1| < \text{cov}(\mathcal{M})$ there is a filter $G \subseteq \mathcal{P}(C_1, T_1, \dot{f})$ meeting $\mathcal{D}_{X,n}(C_1, T_1, \dot{f})$ for all $n \in \omega, X \in C_1$. Then by Corollary 5.6 the pure condition $T_2 = \cup G = \langle r_i : i \in \omega \rangle$ extends $T_1$ and $\forall i \in \omega \forall v \leq i \forall s \subseteq \text{int}(r_i)$ which is $r_i$-positive $\exists w \subseteq s \exists p \in \mathcal{A}_i(\dot{f})$ such that $(v \cup w, T_2) \leq p$.

For all $i \in \omega$ let $g(i)$ be the maximal $k$ such that there are $v \subseteq i$, $w \subseteq \text{int}(r_i)$ and $p \in \mathcal{A}_i(\dot{f})$ such that $p \Vdash \dot{f}(i) = \check{k}$ and $(v \cup w, T_2) \leq p$. We can assume that $g$ is nondecreasing. For all $X \in C_1$ let $J_X = \{i : r_i \subseteq X\}$ and let $F_X$ be the following step function:

$$F_X(\ell) = g(J_X(i + 1)) \text{ iff } \ell \in (J_X(i), J_X(i + 1)]$$

where $J_X(m)$ is the $m$-th element of $J_X$. Since $\mathcal{H}$ is unbounded $\forall X \in C_1 \exists h_X \in \mathcal{H}$ such that $h_X \not\leq^* F_X$. However $|C_1| < |\mathcal{H}|$ and so $\exists h \in \mathcal{H}$ such that $\forall X \in C_1(h_X \leq^* h)$. We can assume that $h$ is nondecreasing.

Note that $\forall X \in C_1(g \leq_0 F_X)$ and so $J = \{i \in \omega : g(i) < h(i)\}$ is infinite. Furthermore $\exists^\omega i \in J_X(F_X(i) < h(i))$ and since $\forall i \in J_X(F_X(i) = g(i))$, the set $I_X = J_X \cap J$ is infinite. Let $R = \langle r_i : i \in J \rangle$ and for all $X \in C_1$ let $R \wedge X := \langle r_i : i \in I_X\rangle$. Then $C' = \{R \wedge X\}_{X \in C_1}$ is a centred family such that $C_1 \cup \{T\} \subseteq Q(C'')$ and $|C'| = |C''|$

Let $C''$ be centred, $C'' \subseteq Q(C'''), a \in [\omega]^{<\omega}$, $k_0 \in \omega$ and let $(b, R') \in Q(C''')$ be an extension of $(a, R)$. There is $i \in J$, $i > k_0$ such that $b \subseteq i$ and $s = \text{int}(R') \cap \text{int}(r_i)$ is $r_i$-positive. Then $\exists w \subseteq s \exists p \in \mathcal{A}_i(\dot{f})$ such that $(b \cup w, T_2) \leq p$. However $R' \setminus w \leq T_2 \setminus w$. Therefore $(b \cup w, R') \leq (b, R')$ and $(b \cup w, R') \leq p$. Let $k \in \omega$ be such that $p \Vdash \dot{f}(i) = \check{k}$. Then by definition of $g$, $k \leq g(i)$ and since $i \in J$, $g(i) < h(i)$. Thus $(b \cup w, R') \Vdash_{Q(C''')} \check{\dot{f}}(i) = \check{k} \leq \check{g}(i) < \check{h}(i)$.

**Lemma 6.2** (Main Lemma). Let $\kappa$ be a regular uncountable cardinal, $\text{cov}(\mathcal{M}) = \kappa$, $\mathcal{H} \subseteq {}^\omega \omega$ an unbounded, $<^*\text{-directed family}, |\mathcal{H}| = \kappa$ and
The consistency of $b = \kappa$ and $s = \kappa^+$

$\forall \lambda < \kappa (2^\lambda \leq \kappa)$. Then there is a centred family $C$, $|C| = \kappa$, such that $\langle \mathcal{H} \text{ is unbounded} \rangle^{V(Q(C))}$ and $Q(C)$ adds a real not split by $V \cap [\omega]^\omega$.

**Proof.** Let $\mathcal{N} = \{ \hat{f}_\alpha \}_{\alpha < \kappa}$ enumerate all names for functions in $\name{\omega}$ for partial orders $Q(C')$ where $C'$ is a centred family, $|C'| < \kappa$ and let $\mathcal{A} = \{ A_{\alpha+1} \}_{\alpha < \kappa}$ enumerate $[\omega]^\omega \cap V$. The centred family $C$ will be obtained by transfinite induction of length $\kappa$. Begin with an arbitrary pure condition $T$ and $C_0 = \{ T \setminus v : v \in [\omega]^\omega \}$. If $\alpha = \beta + 1$ and we have defined the centred family $C_\beta$, let $\hat{g}_\alpha$ be the name with least index in $\mathcal{N} \setminus \{ \hat{g}_\gamma \}_{\gamma < \beta}$ which is a $Q(C_\beta)$-name for a real. If $\hat{g}_\alpha$ is a good $Q(C_\beta)$-name by Theorem 6.1 there is a centered family $C'_\alpha$ extending $C_\beta$, $|C'_\alpha| = |C_\beta|$ and $h_\alpha \in \mathcal{H}$ such that for every centered family $C''$ extending $C'_\alpha$, $\forces_{Q(C'')}[\check{\hat{h}}_\alpha \not\in \check{\hat{g}}_\alpha]$. If $\hat{g}_\alpha$ is not a good $Q(C_\beta)$-name, then by Remark 4.2 there is a centred family $C'_\alpha$ extending $C_\beta$, $|C'_\alpha| = |C_\beta|$ such that $\hat{g}_\alpha$ is not a $Q(C'_\alpha)$-name for a real. In either case, let $T' \in Q(C'_\alpha)$. Then by Lemma 3.13 there is $T_a \leq T'$ such that $\text{int}(T_a) \subseteq A_a$ or $\text{int}(T_a) \subseteq A'_a$ and $T_a \not\subseteq C''$. By Corollary 3.18 applied to the sequence of all final segments of $T_a$ and $|C'_a| < \text{cov}(\mathcal{M})$ there is a centred family $C_a$ such that $C'_a \cup \{ T_a \} \subseteq Q(C_a)$ and $|C_a| = |C'_a|$. If $\alpha$ is a limit let $C_a = \bigcup_{\beta < \alpha} C_\beta$. Then $|C_a| < \kappa$ and $\forall \beta < \alpha (C_a \subseteq Q(C_a))$. With this the inductive construction is complete. Let $C = \bigcup_{\alpha < \kappa} C_a$. Then $C$ is centred, $|C| = \kappa$ and $\forall \alpha < \kappa (C_a \subseteq Q(C))$.

Let $\hat{f}$ be a $Q(C)$-name for a real and let $\alpha < \kappa$ be minimal such that $\hat{f}$ is a $Q(C_a)$-name. Then $\hat{f}$ is a name in $\mathcal{N}$ and there is $\delta < \kappa (\alpha \leq \delta)$ such that $\hat{f}$ is the name with least index in $\mathcal{N} \setminus \{ \hat{g}_\gamma \}_{\gamma < \delta}$ which is a $Q(C_\delta)$-name and so $\hat{f} = \hat{g}_\delta$. Note also that $\hat{f}$ is a good $Q(C_\delta)$-name. Then by the choice of $C_\delta$, $\forces_{Q(C)}[\check{\hat{h}}_\delta \not\in \check{\hat{f}}]$. Let $G$ be a $Q(C)$ generic filter and $\cup G = \bigcup \{ \{ u : \exists T(u, T) \in G \} \}$ for every $\alpha < \kappa$ the set $D_{\alpha+1} = \{ (u, T) \in Q(C) : T \leq T_{\alpha+1} \}$ is dense and so $\cup G \subseteq \text{int}(T_{\alpha+1})$, which implies that $\cup G$ is almost contained in $A_{\alpha+1}$ or in $A'_a$.

The proof of Theorem 6.3 can be found in [9].

**Theorem 6.3.** Let $\mathcal{H} \subseteq \name{\omega}$ be unbounded family such that $\forall \mathcal{H}' \in [\mathcal{H}]^{\leq \omega} \exists h \in \mathcal{H}(\mathcal{H}' \not\subseteq h)$ and let $\langle \mathbb{P}_\gamma : \gamma \leq \alpha \rangle$ be a finite support iteration of ccc forcing notions of length $\alpha$, cf($\alpha$) = $\omega$ such that $\forall \gamma < \alpha (\mathcal{H} \text{ is unbounded})^{V_{\mathbb{P}}}$, then $\langle \mathcal{H} \text{ is unbounded} \rangle^{V_{\mathbb{P}}}$.

The proof of Lemma 6.4 can be found in [2].

**Lemma 6.4.** Let $\kappa$ be a regular uncountable cardinal, $\mathcal{H} \subseteq \name{\omega}$ unbounded, $\ast$-directed family, $|\mathcal{H}| = \kappa$. Then for every partial order $\mathbb{P}$ of size less than $\kappa$, $\langle \mathcal{H} \text{ is unbounded} \rangle^{V_{\mathbb{P}}}$. 
Recall that if \( \mathcal{A} \subseteq {}^\omega \omega \) is infinite the Hechler forcing \( \mathbb{H}(\mathcal{A}) \) (see [8]) consists of all pairs \( (s, F) \) where \( s \in \bigcup_{n \in \omega} {}^n \omega \) and \( F \in [\mathcal{A}]^{< \omega} \), with extension relation \( (s_1, F_1) \leq (s_2, F_2) \) iff \( s_2 \subseteq s_1, F_2 \subseteq F_1 \) and \( \forall f \in F_2 \forall k \in \text{dom}(s_1) \setminus \text{dom}(s_2) \) we have \( s_1(k) \geq f(k) \). Note that \( \mathbb{H}(\mathcal{A}) \) is \( \sigma \)-centred, adds a real dominating \( \mathcal{A} \) and and \( |\mathbb{H}(\mathcal{A})| = |\mathcal{A}| \).

**Theorem 6.5 (GCH).** Let \( \kappa \) be a regular uncountable cardinal. Then there is a ccc generic extension in which \( b = \kappa < s = \kappa^+ \).

**Proof.** Obtain a model \( V \) of \( b = c = \kappa \) by adding \( \kappa \) Hechler reals (see [7]) and let \( \mathcal{H} = V \cap {}^\omega \omega \). Inductively define a finite support iteration \( \langle \mathbb{P}_\alpha : \alpha \leq \kappa^+ \rangle \) of ccc forcing notions as follows. Suppose \( \forall \beta < \alpha, \mathbb{P}_\beta \) has been defined so that in \( V^{\mathbb{P}_\beta} \), \( \mathcal{H} \) is unbounded, \(<^*\) directed and \( \forall \lambda < \kappa(2^\lambda \leq \kappa) \). If \( \alpha \) is a limit, let \( \mathbb{P}_\alpha \) be the finite support iteration of \( \langle \mathbb{P}_\beta : \beta < \alpha \rangle \). Then \( \mathbb{P}_\alpha \) is ccc and by Theorem 6.3 the inductive hypothesis holds in \( V^{\mathbb{P}_\alpha} \).

If \( \alpha = \beta + 1 \) and \( \mathbb{P}_\beta \) has been defined, then let \( V_\beta = V^{\mathbb{P}_\beta} \) and let \( \mathbb{H}_1 \) be the forcing notion for adding \( \kappa \) Cohen reals. Then in \( V^{\mathbb{P}_\beta}_{\mathbb{H}_1} \) the family \( \mathcal{H} \) is unbounded, \(<^*\) directed, \( \forall \lambda < \kappa(2^\lambda \leq \kappa) \) and \( \text{cov}(\mathcal{M}) = \kappa \). Therefore in \( V^{\mathbb{P}_\beta}_{\mathbb{H}_1} \) the hypothesis of Lemma 6.2 holds and so there is a centered family \( C \) such that \( Q(C) \) adds a real not split by \( V^{\mathbb{P}_\beta}_{\mathbb{H}_1} \cap [\omega]^{< \omega} \) and preserves \( \mathcal{H} \) unbounded. Let \( \mathbb{H}_2 \) be a \( \mathbb{H}_1 \)-name for \( Q(C) \) and in \( V^{\mathbb{P}_\beta}_{\mathbb{H}_1 \ast \mathbb{H}_2} \) let \( \mathcal{A} \subseteq V_\beta \cap {}^\omega \omega \) be an unbounded family of cardinality less than \( \kappa \). Let \( \mathbb{H}_3 \) be a \( \mathbb{H}_1 \ast \mathbb{H}_2 \) name for \( \mathbb{H}(\mathcal{A}) \). Then in \( V^{\mathbb{P}_\beta}_{\mathbb{H}_1 \ast \mathbb{H}_2} \ast \mathbb{H}_3 \) the family \( \mathcal{A} \) is dominated and since \( |\mathbb{H}(\mathcal{A})| < \kappa, \mathcal{H} \) remains unbounded. Let \( \mathbb{Q}_\beta \) be a \( \mathbb{P}_\beta \)-name for \( (\mathbb{H}_1 \ast \mathbb{H}_2) \ast \mathbb{H}_3 \), and let \( \mathbb{P}_\alpha = \mathbb{P}_\beta \ast \mathbb{Q}_\beta \).

Let \( \mathbb{P} = \mathbb{P}_\alpha^+ \). Let \( G \) be a \( \mathbb{P} \)-generic filter and let \( \mathcal{A} \subseteq [\omega]^{< \omega} \cap V[G] \), \( |\mathcal{A}| < \kappa^+ \). Then \( \exists \alpha < \kappa^+ \) such that \( \mathcal{A} \subseteq V[G_\alpha] \) where \( G_\alpha = G \cap \mathbb{P}_\alpha \). By the inductive construction of \( \mathbb{P} \), in \( V[G_{\alpha+1}] \) there is a real not split by \( \mathcal{A} \). Therefore \( V^\mathbb{P} \models s = \kappa^+ \). By Theorem 6.3 and the construction of \( \mathbb{P} \) the family \( \mathcal{H} \) is unbounded in \( V^\mathbb{P} \). Since every family of reals in \( V^\mathbb{P} \) of size less than \( \kappa \) is obtained at some initial stage of the iteration, a suitable bookkeeping device can guarantee that any such family is bounded and so \( V^\mathbb{P} \models b = \kappa \). \( \square \)
